Metaphyseal osteoblast function is modulated by systemic OPG and RANKL. Receptor activator of nuclear factor kappa B (RANK) is an essential mediator of the osteoclast-osteoblast equilibrium in the adult skeleton. Its ligand, RANKL, is expressed by osteoblasts and bone marrow stromal cells. Osteoprotegerin (OPG) is a secreted, single-pass transmembrane protein that acts as a decoy receptor for RANKL and prevents its binding to RANK. The development of a

RANK-RANKL transgenic mouse model has demonstrated that in the absence of RANK, the differentiation of osteoclasts is severely impaired in the bone. However, the role of OPG in the regulation of bone cell activity is less clear. In the current study, we demonstrate that overexpression of OPG in transgenic mice severely impairs the proliferation and differentiation of the osteoblastic lineage, and strongly suppresses the differentiation of the osteoclast lineage in vivo. Conversely, systemic administration of OPG in transgenic mice that overexpress RANKL enhances bone formation, and enhances the development of osteoclasts. Collectively, these data suggest that OPG is a bone-forming factor that is sensitive to the levels of RANKL expression in the skeleton.AC-DC converter modules are used to produce a regulated DC output voltage from a low-voltage AC input voltage. The conversion includes at least two power switches, which are switched on and off periodically. Each power switch is connected to a capacitor for energy storage. In one known type of power module, a DC input voltage is rectified and filtered to produce a DC output voltage. A control circuit monitors the DC output voltage and supplies a control signal to a corresponding switch to control switching of the corresponding power switch. The switching is periodic, and the resulting periodic flow of energy between the energy storage capacitor and the DC output is used to produce a ripple voltage that increases with increasing ripple energy, and a ripple current that increases with increasing ripple energy. The ripple voltage is usually limited in magnitude by a ripple voltage clamp, and the ripple current is usually limited in magnitude by 82157476af
